

Module 4F12: Computer Vision

Examples Paper 1

Straightforward questions are marked †

*Tripos standard (but not necessarily Tripos length) questions are marked **

1. † *Images*

Images are stored as pixel arrays of quantised intensity values. Typically each pixel has a brightness value in the range 0 (black) to 255 (white), and is stored as a single byte (8 bits). Compute the storage requirements (in bytes per second) for a stereo pair of HD video cameras grabbing grey-level images of size 1920×1080 pixels at 25 frames per second. Approximately how many pages of text require the same amount of storage as one second of stereo video?

2. * *Smoothing by convolution with a Gaussian*

A commonly used 1D smoothing filter is the Gaussian:

$$g_{\sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{x^2}{2\sigma^2}\right)$$

where σ determines the size of the filter. Show that repeated convolutions with a series of 1D Gaussians, each with a particular standard deviation σ_i , is equivalent to a single convolution with a Gaussian of variance $\sum_i \sigma_i^2$.

3. *Generating the Gaussian filter kernel*

A discrete approximation to a 1D Gaussian can be obtained by sampling the function $g_{\sigma}(x)$. In practice, samples are taken uniformly until the truncated values at the tails of the distribution are less than 1/1000 of the peak value.

- (a) For $\sigma = 1$, show that the filter obtained in this way has a size of 7 pixels and coefficients given by:

0.004	0.054	0.242	0.399	0.242	0.054	0.004
-------	-------	-------	-------	-------	-------	-------

What property of the coefficients ensures that regions of uniform intensity are unaffected by smoothing?

- (b) Using the same truncation criterion, what would be the size of the discrete filter kernel for $\sigma = 5$? Show that, in general, the size of the kernel can be approximated as $2n + 1$ pixels, where n is the nearest integer to $3.7\sigma - 0.5$.
- (c) The filter is used to smooth an image as part of an edge detection procedure. What factors affect the choice of an appropriate value for σ ?

4. † *Discrete convolution*

The following row of pixels is smoothed with the discrete 1D Gaussian kernel given in question 3(a) ($\sigma = 1$). Calculate the smoothed value of the pixel with intensity 118.

46	45	45	48	50	53	55	57	77	99	118	130	133	134	133	132	132	132	133
----	----	----	----	----	----	----	----	----	----	-----	-----	-----	-----	-----	-----	-----	-----	-----

5. *Derivative of convolution theorem*

- (a) Show that smoothing an intensity signal with a Gaussian and then differentiating the smoothed signal is equivalent to convolution with the derivative of a Gaussian:

$$\frac{d}{dx}[g_\sigma(x) * I(x)] = g'_\sigma(x) * I(x)$$

where $g'_\sigma(x)$ is the first derivative of the Gaussian function.

- (b) Hence, or otherwise, show how “edges” in an intensity function $I(x)$ can be localised at the zero-crossings of $g''_\sigma(x) * I(x)$, where $g''_\sigma(x)$ is the second derivative of the Gaussian function.

6. *Differentiation and 1D edge detection*

Show how an approximation to the first-order spatial derivative of $I(x)$ can be obtained by convolving samples of $I(x)$ with the kernel

1/2	0	-1/2
-----	---	------

The smoothed row of pixels in question 4 is shown below.

x	x	x	48	50	53	56	64	79	98	115	126	132	133	133	132	x	x	x
---	---	---	----	----	----	----	----	----	----	-----	-----	-----	-----	-----	-----	---	---	---

Find the first order derivatives and localise the intensity discontinuity.

7. *Decomposition of 2D convolution*

Smoothing a 2D image involves a 2D convolution with a 2D Gaussian:

$$G_\sigma(x, y) = \frac{1}{2\pi\sigma^2} \exp - \left(\frac{x^2 + y^2}{2\sigma^2} \right)$$

Show that this can be performed by two 1D convolutions: i.e.

$$G_\sigma(x, y) * I(x, y) = g_\sigma(x) * [g_\sigma(y) * I(x, y)]$$

What is the advantage of performing two 1D convolutions instead of a 2D convolution?

8. * *Isotropic and directional edge finders*

The Marr–Hildreth operator convolves the image with a discrete version of the Laplacian of a Gaussian and then localises edges at the resulting zero-crossings. Show that the Laplacian of a Gaussian is an isotropic (ie. rotationally symmetric) operator. Hence explain why the operator produces zero-crossings along an ideal step edge.

The Canny operator is a directional edge finder. It first localises the orientation of the edge by computing

$$\hat{\mathbf{n}} = \frac{\nabla (G_\sigma(x, y) * I(x, y))}{|\nabla (G_\sigma(x, y) * I(x, y))|}$$

and then searches for a local maximum of $|\nabla (G_\sigma * I)|$ in the direction $\hat{\mathbf{n}}$. Show that this is equivalent to finding zero-crossings in the directional second derivative of $(G_\sigma * I)$ in the direction $\hat{\mathbf{n}}$, ie. finding zero crossings in

$$\frac{\partial^2 (G_\sigma * I)}{\partial s^2}$$

where s is a length parameter in the direction $\hat{\mathbf{n}}$.

What are the advantages and disadvantages of isotropic and directional operators?

9. * *Auto-correlation and corner detection*[Tripos 2012]

- (a) Show that the weighted sum of squared differences (SSD) between a patch (window W) of pixels in image $I(x, y) = I(\mathbf{x})$ and another patch of pixels taken by shifting the window by a small amount in the direction \mathbf{n} can be expressed approximately by:

$$C(\mathbf{n}) = \sum_{\mathbf{x} \in W} w(\mathbf{x})(I(\mathbf{x} + \mathbf{n}) - I(\mathbf{x}))^2 \approx \sum_{\mathbf{x} \in W} w(\mathbf{x})I_n^2$$

where $I_n = \nabla I(\mathbf{x}) \cdot \mathbf{n}$.

- (b) Hence show that the weighted SSD can be represented by:

$$C = \mathbf{n}^T \mathbf{A} \mathbf{n}$$

where A is matrix of smoothed intensity gradients (sometimes called a second-moment or autocorrelation matrix) defined as follows:

$$\mathbf{A} \equiv \begin{bmatrix} \langle I_x^2 \rangle & \langle I_x I_y \rangle \\ \langle I_x I_y \rangle & \langle I_y^2 \rangle \end{bmatrix}$$

where $I_x \equiv \partial I / \partial x$, $I_y \equiv \partial I / \partial y$ and $\langle \rangle$ denotes a 2-dimensional weighting (smoothing) operation.

- (c) How are the directional derivatives computed? How are the 2D weighted (smoothed) values obtained?

(d) Show how A can be analysed to detect corner features and give details of the Harris-Stephens corner detection algorithm.

(Note — Part IA Maths revision) For a real, symmetric $n \times n$ matrix A the minimum and maximum values of

$$C = \frac{\mathbf{n}^T A \mathbf{n}}{\mathbf{n}^T \mathbf{n}}$$

are given by

$$\lambda_1 \leq C \leq \lambda_n$$

where λ_1 and λ_n are the minimum and maximum eigenvalues of A respectively.

10. * *Feature detection and scale space* [Tripos 2011]

Consider an algorithm to detect interest points (features of interest) in a 2-D image for use in matching.

- (a) Show how different resolutions of the image can be represented efficiently in an *image pyramid*. Your answer should include details of the implementation of smoothing within an octave and subsampling of the image between octaves.
- (b) How can *band-pass* filtering at different scales be implemented efficiently using the image pyramid? Show how image features such as *blob-like* shapes can be localized in both position and scale using band-pass filtering.
- (c) Explain how interest points in different images can be matched. Give details of 3 suitable descriptors.

Suitable past Tripos questions: Q1 on all exams 1996-2015
